The project

Chapter 3

Planning the project

3.1 What Do We Need?

- The ability to add custom syntax (access to the tokenizer / parser)
- Some semantic analysis.

3.2 Syntax

For the implementation of PT we need syntax for the following:

- Defining packages (`package` in PTj)
- Defining templates (`template` in PTj)
- Instantiating templates (`inst` in PTj)
- Renaming classes (`=>` in PTj)
- Renaming methods (`->` in PTj)
- Additions to classes (`addto` in PTj)

`template` and `inst` are both not in use nor reserved in the ECMAScript standard or in TypeScript, and can therefore be used in PTScript(Midlertidlig navn) without any issues.

The keyword `package` in TS / ES is as of yet not in use, however the ECMAScript standard has reserved it for future use. In order to "future proof" our implementation we should avoid using this reserved keyword, as it could have some conflicts with a potential future implementation of packages in ECMAScript. It could also be beneficial to not share the keyword in order avoid creating confusion between the future ES packages and PT Packages. `module` is also a keyword that could be used to describe a PT package, however this is already used in the ES standard, and should therefore also be avoided for similar reasons to `package`, to avoid confusion. We will therefore use (`pack` eller `bundle`? Må nok se litt mer på dette) instead.

For renaming classes PTj uses `=>`, however in ES this is used in arrow-functions[1]. To avoid confusion and a potentially ambiguous grammar we will have to choose a different syntax for renaming classes. PTj, for historical purposes, uses a different operator (`->`) for renaming class methods, however for keeping PTScript(Midlertidlig navn) simple we will stick to only having one common operator for renaming.

ECMAScript currently supports renaming of destructured fields using the `:`(colon) operator and aliasing imports using the keyword `as`. Even though we opted to choose a different keyword for packages, we will here re-use the already existing `as` keyword for renaming as the concepts are so closely related.

PTScript(Midlertidlig navn):

```
template T {
  class A {
    function f() : String {
      ...
    }
  }
}

pack P {
  inst T with A as A (f as g); // Function overloading not supported
  addto A {
    i : number = 0;
  }
}
```

PTj:

```
template T {
  class A {
    String f() {
      ...
    }
  }
}

package P {
  inst T with A => A (f() -> g());
  addto A {
    int i = 0;
  }
}
```

3.3 TypeScript vs JavaScript / ECMAScript

3.4 Choosing the right approach

Before jumping into a project of this magnitude it is important to find out what approach to use. The goal of this project is to extend TypeScript with the Package Templates language mechanism, this can be achieved as following:

- Making a fork of the TypeScript compiler
- Making a preprocessor for the TypeScript compiler
- Making a compiler plugin / transform
- Making a custom compiler from scratch

3.4.1 Preprocessor for the TypeScript Compiler

More work than ex plugin / transformer.

3.4.2 TypeScript Compiler Plugin / Transform

As of the time of writing this the official TypeScript compiler does not support compile time plugins. The plugins for the TypeScript compiler is, as the TypeScript compiler wiki specifies, "for changing the editing experience only"[3]. However there are alternatives that do enable compile time plugins / transformers;

- ts-loader[5], for the webpack ecosystem
- Awesome Typescript Loader[4], for the webpack ecosystem. Deprecated
- ts-node[6], REPL / runtime
- ttypescript[2], TypeScript tool TODO: Les mer på dette

Unfortunately ts-loader, Awesome Typescript Loader and ts-node does not support adding custom syntax, as it only transforms the AST produced by the TypeScript compiler. Because of this they are not a viable option for our use-case and will therefore be discarded.

3.4.3 Babel plugin

Babel isn't strictly for TypeScript, but for JavaScript as a whole, however we could write our plugin to be dependent on the TypeScript transformation plugin.

Making a Babel plugin will make it very accessible as most web-projects use Babel, and the upkeep is cheap, as plugins are loosely coupled with the core.

In order for a Babel plugin to support custom syntax it has to provide a custom parser, a fork of the Babel parser. Through this we can extend the TypeScript syntax with our syntax for PT. This is all hidden away from the user, as this custom parser is a dependency of our Babel plugin.

Seeing as we have to make a fork of the parser in order to solve our problem, the upkeep will not be as cheap as first anticipated. However being able to have most of the logic loosely coupled with the compiler core it will still make it easier to keep updated than through a fork of the TypeScript compiler.

TODO: Er det støttet å bruke flere plugins med forskjellige parsere? E.g. babel-plugin-typescript + vårt babel plugin?

3.4.4 TypeScript Compiler Fork

Possible, however not as accessible as other alternatives and will make upkeep expensive.

The TypeScript compiler is a monolith. It has about 2.5 million lines of code, and therefore has a quite steep learning curve to get into. If we were to go with this route it would be quite hard to keep up with the TypeScript updates, as updates to the compiler might break our implementation. However as we have seen, going the plugin / transform route also requires us to fork the underlying compiler and make changes to it, however with the majority of the implementation being loosely coupled it would still make it easier to keep up-to-date. That being said it will probably be a lot easier to do semantic analysis in a fork of the TypeScript compiler vs in a plugin / transform.
